## Strategic Form Games

## Finite Games

an $N$ player game $i=1 \ldots N$
$P(S)$ are probability measure on $S$
finite strategy spaces $S_{i}$
$\sigma_{i} \in \Sigma_{i} \equiv P\left(S_{i}\right)$ are mixed strategies
$s \in S \equiv \times_{i=1}^{N} S_{i}$ are the strategy profiles, $\quad \sigma \in \Sigma \equiv \times_{i=1}^{N} \Sigma_{i}$
other useful notation $s_{-i} \in S_{-i} \equiv \times_{j \neq i} S_{j}$

$$
\sigma_{-i} \in \Sigma_{-i} \equiv \times_{j \neq i} \Sigma_{j}
$$

$u_{i}(s)$ payoff or utility

$$
u_{i}(\sigma) \equiv \sum_{s \in S} u_{i}(s) \prod_{j=1}^{N} \sigma_{j}\left(s_{j}\right) \text { is expected utility }
$$

## Dominance and Rationalizability

$\sigma_{i}$ weakly (strongly) dominates $\sigma_{i}^{\prime}$ if

$$
u_{i}\left(\sigma_{i}, s_{-i}\right) \geq(>) u_{i}\left(\sigma_{i}^{\prime}, s_{-i}\right) \text { with at least one strict }
$$

## Prisoner's Dilemma Game

|  | R |
| :--- | :--- |
|  | $L$ |
| D | 2,2 0,3 <br> 3,0 1,1 |

a unique dominant strategy equilibrium ( $\mathrm{D}, \mathrm{L}$ )
this is Pareto dominated by $(\mathrm{U}, \mathrm{R})$ does it really occur??

## Public Goods Experiment

Players randomly matched in pairs
May donate or keep a token
The token has a fixed commonly known public value of 15
It has a randomly drawn private value uniform on 10-20
V=private gain/public gain
So if the private value is 20 and you donate you lose 5 , the other player gets 15 ; $\mathrm{V}=-1 / 3$
If the private value is 10 and you donate you get 5 the other player gets 15 ; $V=+1 / 3$
Data from Levine/Palfrey, experiments conducted with caltech undergraduates
Based on Palfrey and Prisbey

| V | donating a token |
| :--- | :--- |
| 0.3 | $100 \%$ |
| 0.2 | $92 \%$ |
| 0.1 | $100 \%$ |
| 0 | $83 \%$ |
| -0.1 | $55 \%$ |
| -0.2 | $13 \%$ |
| -0.3 | $20 \%$ |

## Second Price Auction

a single item is to be auctioned.
value to the seller is zero.
$i=1, \ldots, N$ buyers
value $v_{i}>0$ to buyer $i$.
each buyer submits a bid $b_{i}$
the item is sold to the highest bidder at the second highest bid
bidding your value weakly dominates

## Iterated Dominance

example of iterated weak dominance

|  | L | R-I | R-r |
| :--- | :--- | :--- | :--- |
| U-u | $-1,-1$ | 2,0 | 1,1 |
| U-d | $-1,-1$ | $1,-1$ | 0,0 |
| D | 1,1 | 1,1 | 1,1 |

Eliminate U-d
Eliminate L
Eliminate D (or) Eliminate R-I

## Eliminate R-I

Notice that there can be more than one answer for iterated weak dominance

Not for iterated strong dominance

## Cournot Oligopoly

$\pi_{i}=\left[17-\left(x_{i}+x_{-i}\right)\right] x_{i}-x_{i} ;$ reaction function $x_{i}=8-\frac{x_{-i}}{2}$

## Nash Equilibrium

## Definition

players can anticipate on another's strategies
$\sigma$ is a Nash equilibrium profile if for each $i \in 1, \ldots N$
$u_{i}(\sigma)=\max _{\sigma_{i}^{\prime}} u_{i}\left(\sigma_{i}^{\prime}, \sigma_{-i}\right)$

Theorem: a Nash equilibrium exists in a finite game

This theorem fails in pure strategies: consider matching pennies Holmes and Moriarity
this is more or less why Kakutani's fixed point theorem was invented:
An upper hemi-continuous (UHC) convex valued correspondence $B$ from a convex subset $\Sigma \subseteq \Re^{n}$ to itself has a fixed point $\sigma \in B(\sigma)$

A correspondence $B: \Sigma \Rightarrow \Sigma$ is UHC means if $\sigma^{n} \rightarrow \sigma$ such that $b^{n} \in B\left(\sigma^{n}\right) \rightarrow b$ then $b \in B(\sigma)$.

## Proof: Let $B_{i}(\sigma)$ be the set of best responses of $i$ to $\sigma_{-i}$

convex valued: convex combinations of a best response is a best response. Specifically, since you must be indifferent between all pure strategies played with positive probability, the best response set is the set of all convex combinations of the pure strategies that are best responses.

UHC: $b_{i}^{n} \in B_{i}\left(\sigma_{-i}^{n}\right) \rightarrow b_{i}$ means that $u^{i}\left(b_{i}^{n}, \sigma_{-i}^{n}\right) \geq u^{i}\left(\sigma_{i}, \sigma_{-i}^{n}\right)$. Suppose the converse that $b \notin B(\sigma)$. This means for some $\hat{\sigma}_{i}$ that $u^{i}\left(\hat{\sigma}_{i}, \sigma_{-i}\right)>u^{i}\left(b_{i}, \sigma_{-i}\right)$. Since $\sigma_{-i}^{n} \rightarrow \sigma_{-i}$ for $n$ sufficiently large, since $u^{i}$ is continuous (multi-linear in fact) in $\sigma_{-i}, u^{i}\left(\hat{\sigma}_{i}, \sigma_{-i}^{n}\right)>u^{i}\left(b_{i}, \sigma_{-i}^{n}\right)$. Since $b_{i}^{n} \rightarrow b_{i}$, since $u^{i}$ is continuous (linear in fact) in $\sigma_{i}$, also for $n$ sufficiently large $u^{i}\left(\hat{\sigma}_{i}, \sigma_{-i}^{n}\right)>u^{i}\left(b_{i}^{n}, \sigma_{-i}^{n}\right)$. This contradicts $b_{i}^{n} \in B_{i}\left(\sigma_{-i}^{n}\right)$.
"a sequence of best-responses converges to a best-response"

## Best Response Correspondence Example

|  | $\mathrm{L}\left(\sigma_{2}(L)=q\right)$ | R |
| :--- | :--- | :--- |
| $\mathrm{U}\left(\sigma_{1}(U)=p\right)$ | 1,1 | 0,0 |
| D |  | 1,1 |
|  | 0,0 |  |

## Mixed Strategies: The Kitty Genovese Problem

Description of the problem

Model:
$n$ people all identical
benefit if someone calls the police is $x$
cost of calling the police is 1
Assumption: $x>1$

Look for symmetric mixed strategy equilibrium where $p$ is probability of each person calling the police
$p$ is the symmetric equilibrium probability for each player to call the police
each player $i$ must be indifferent between calling the police or not if $i$ calls the police, gets $x-1$ for sure.
If $i$ doesn't, gets 0 with probability $(1-p)^{n-1}$, gets $x$ with probability $1-(1-p)^{n-1}$
so indifference when $x-1=x\left(1-(1-p)^{n-1}\right)$
solve for $p=1-(1 / x)^{1 /(n-1)}$
probability police is called

$$
1-(1-p)^{n}=1-\left(\frac{1}{x}\right)^{\frac{n}{n-1}}
$$

## probability police are called

$x=10$

## Coordination Games

|  | L |
| :--- | :--- |
|  | $R$ |
| D | 1,1 0,0 <br> 0,0 1,1 |

three equilibria (U,L) (D,R) (.5U,.5R)
too many equilibria?? introspection possible?
the rush hour traffic game - introspection clearly impossible, yet we seem to observe Nash equilibrium
equilibrium through learning?

## Coordination Experiments

Van Huyck, Battalio and Beil [1990]
Actions $A=\{1,2, \ldots \bar{e}\}$
Utility $u\left(a_{i}, a_{-i}\right)=b_{0} \min \left(a_{j}\right)-b a_{i}$ where $b_{0}>b>0$
Everyone doing $a^{\prime}$ the same thing is always a Nash equilibrium
$a^{\prime}=\bar{e}$ is efficient
the bigger is $a^{\prime}$ the more efficient, but the "riskier"
a model of "riskier" some probability of one player playing $a^{\prime}=1$ story of the stag-hunt game

$$
\bar{e}=7,14-16 \text { players }
$$

treatments:

$$
\text { A } b_{0}=2 b
$$

$$
\text { B } b=0
$$

In final period treatment A:
77 subjects playing $a_{i}=1$
30 subjects playing something else
minimum was always 1

In final period treatment B :
87 subjects playing $a_{i}=7$
0 playing something else
with two players $a_{i}=7$ was more common

## 1/2 Dominance

Coordination Game

|  | $\mathrm{L}\left(p_{2}\right)$ | R |
| :--- | :--- | :--- |
| $\mathrm{U}\left(p_{1}\right)$ | 2,2 | $-10,0$ |
| D | 1,1 |  |

risk dominance:
indifference between U,D

$$
\begin{aligned}
& 2 p_{2}-10\left(1-p_{2}\right)=\left(1-p_{2}\right) \\
& 13 p_{2}=11, p_{2}=11 / 13
\end{aligned}
$$

if $U, R$ opponent must play equilibrium w/ 11/13
if $D, L$ opponent must play equilibrium w/ $2 / 13$
$1 / 2$ dominance: if each player puts weight of at least $1 / 2$ on equilibrium strategy, then it is optimal for everyone to keep playing equilibrium
(same as risk dominance in $2 \times 2$ games)

## Trembling Hand Perfection

$\sigma$ is trembling hand perfect if there is a sequence $\sigma^{n} \gg 0, \sigma^{n} \rightarrow \sigma$ such that
if $\sigma^{i}\left(s^{i}\right)>0$ then $s^{i}$ is a best response to $\sigma^{n}$
Note: thp is necessarily a Nash equilibrium

## Examples:

strict Nash equilibrium is always thp
completely mixed Nash equilibrium is always thp

## Example of Non-Trembling Hand Perfect Equilibrium

|  | $l$ <br> L |  |
| :--- | :--- | :--- |
| U | $l$  <br> $-1,-1$ $2^{*}, 0^{*}$ <br>  $0^{*}, 2^{*}$ | $0,2^{*}$ |

## Correlated Equilibrium

Chicken

| 6,6 | 2,7 |
| :--- | :--- |
| 7,2 | 0,0 |

three Nash equilibria $(2,7),(7,2)$ and mixed equilibrium w/ probabilities (2/3,1/3) and payoffs
(4 2/3, 4 2/3)

| 6,6 | 2,7 |
| :--- | :--- |
| 7,2 | 0,0 |

correlated strategy

| $1 / 3$ | $1 / 3$ |
| :--- | :--- |
| $1 / 3$ | 0 |

is a correlated equilibrium giving utility $(5,5)$
What is public randomization?

## Approximate Equilibria and Near Equilibria

- exact: $u_{i}\left(s_{i} \mid \sigma_{-i}\right) \geq u_{i}\left(s_{i}^{\prime} \mid \sigma_{-i}\right)$ approximate: $u_{i}\left(s_{i} \mid \sigma_{-i}\right)+\varepsilon \geq u_{i}\left(s_{i}^{\prime} \mid \sigma_{-i}\right)$
- Approximate equilibrium can be very different from exact equilibrium

Radner's work on finite repeated PD gang of four on reputation
upper and lower hemi-continuity

A small portion of the population playing "non-optimally" may significantly change the incentives for other players causing a large shift in equilibrium behavior.

## Quantal Response Equilibrium

(McKelvey and Palfrey)
propensity to play a strategy
$p_{i}\left(s_{i}\right)=\exp \left(\lambda_{i} u_{i}\left(s_{i}, \sigma_{-i}\right)\right)$
$\sigma_{i}\left(s_{i}\right)=p_{i}\left(s_{i}\right) / \sum_{s_{i}{ }^{\prime}} p_{i}\left(s_{i}{ }^{\prime}\right)$
as $\lambda_{i} \rightarrow \infty$ approaches best response
as $\lambda_{i} \rightarrow 0$ approaches uniform distribution

## Smoothed Best Response Correspondence Example

|  | $\mathrm{L}\left(\sigma_{2}(L)=q\right)$ | R |
| :--- | :--- | :--- |
| $\mathrm{U}\left(\sigma_{1}(U)=p\right)$ | 1,1 | 0,0 |
| D | 0,0 | 1,1 |
|  |  |  |

## Experimental Example

## Goeree and Holt: Matching Pennies

## Symmetric

|  | $50 \%(48 \%)$ | $50 \%(52 \%)$ |
| :--- | :--- | :--- |
| $50 \%(48 \%)$ | 80,40 | 40,80 |
| $50 \%(52 \%)$ | 40,80 | 80,40 |

|  | $12.5 \%$ (16\%) | $87.5 \%$ (84\%) |
| :--- | :--- | :--- |
| $50 \%$ (96\%) | 320,40 | 40,80 |
| $50 \%$ (4\%) | 40,80 | 80,40 |

|  | $(80 \%)$ | $(20 \%)$ |
| :--- | :--- | :--- |
| $50 \%(8 \%)$ | 44,40 | 40,80 |
| $50 \%$ (92\%) | 40,80 | 80,40 |
